Abstract

In the combinatorial study of the coefficients of a bivariate polynomial that generalizes both the length and the reflection length generating functions for finite Coxeter groups, Petersen introduced a new Mahonian statistic *sor*, called the sorting index. Petersen proved that the pairs of statistics (sor, cyc) and $(inv, rl-min)$ have the same joint distribution over the symmetric group, and asked for a combinatorial proof of this fact. In answer to the question of Petersen, we observe a connection between the sorting index and the B-code of a permutation defined by Foata and Han, and we show that the bijection of Foata and Han serves the purpose of mapping $(inv, rl-min)$ to (sor, cyc) . We also give a type B analogue of the Foata-Han bijection, and we derive the equidistribution of $(inv_B, Lmap_B, Rmil_B)$ and $(sor_B, Lmap_B, Cyc_B)$ over signed permutations. So we get a combinatorial interpretation of Petersen's equidistribution of $(inv_B, nmin_B)$ and (sor_B, l'_B) . Moreover, we show that the six pairs of set-valued statistics $(Cyc_B, Rmil_B)$, $(Cyc_B, Lmap_B)$, $(Rmil_B, Lmap_B)$, $(Lmap_B, Rmil_B)$, $(Lmap_B, Cyc_B)$ and $(Rmil_B, Cyc_B)$ are equidistributed over signed permutations. For Coxeter groups of type D , Petersen showed that the two statistics inv_D and sor_D are equidistributed. We introduce two statistics $nmin_D$ and $\tilde{l}'_D$ for elements of D_n and we prove that the two pairs of statistics $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$ are equidistributed.

1 Introduction

This paper is concerned with a combinatorial study of the Mahonian statistic *sor*, introduced by Petersen [10]. This statistic is also interpreted by Wilson [11, 12] as the total distance moved rightward in the random generation of a permutation based on the Fisher-Yates shuffle algorithm.

Let $[n] = \{1, 2, \dots, n\}$. The set of permutations of $[n]$ is denoted by S_n . Let us recall the definition of the sorting index of a permutation σ in S_n . Notice that σ has a unique

decomposition into transpositions

$$\sigma = (i_1, j_1)(i_2, j_2) \cdots (i_k, j_k)$$

such that

$$j_1 < j_2 < \cdots < j_k$$

and

$$i_1 < j_1, i_2 < j_2, \dots, i_k < j_k.$$

The sorting index is defined by

$$sor(\sigma) = \sum_{r=1}^k (j_r - i_r).$$

Based on the cycle decomposition of a permutation, Foata and Han [6] introduced the B-code of a permutation. We observe that the sorting index of a permutation can be easily expressed in terms of its B-code. Given a permutation $\sigma \in S_n$ with B-code $b = (b_1, b_2, \dots, b_n)$, it can be seen that the sorting index of σ is given by

$$sor(\sigma) = \sum_{i=1}^n (i - b_i).$$

Petersen [10] has shown that the sorting index sor is a Mahonian statistic, that is, it has the same distribution as the number of inversions. He also introduced the sorting indices for Coxeter groups of type B and type D and showed that they are Mahonian as well.

Let us recall some notation and terminology. For $n \geq 1$, given a permutation $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n \in S_n$, a pair (σ_i, σ_j) is called an inversion if $i < j$ and $\sigma_i > \sigma_j$. Let $inv(\sigma)$ denote the number of inversions of σ . An element σ_i is said to be a right-to-left minimum of σ if $\sigma_i < \sigma_j$ for all $j > i$. The number of right-to-left minima of σ is denoted by $rl-min(\sigma)$. The number of elements of σ that are not right-to-left minima is denoted by $nmin(\sigma)$. Similarly, one can define a left-to-right maximum. The number of left-to-right maxima of σ is denoted by $lr-max(\sigma)$. The number of cycles of σ is denoted by $cyc(\sigma)$. The reflection length of σ , denoted $l'(\sigma)$, is the minimal number of transpositions needed to express σ .

By using two factorizations of the diagonal sum, i.e., $\sum_{\sigma \in S_n} \sigma$, in the group algebra $\mathbb{Z}[S_n]$, Petersen has shown that (sor, cyc) and $(inv, rl-min)$ have the same joint distribution by deriving the following generating function formulas:

$$\sum_{\sigma \in S_n} q^{sor(\sigma)} t^{cyc(\sigma)} = \sum_{\sigma \in S_n} q^{inv(\sigma)} t^{rl-min(\sigma)} = t(t+q) \cdots (t+q+q^2+\cdots+q^{n-1}).$$

He raised the question of finding a bijection that maps a permutation with inversion number k to a permutation with sorting index k . We find that a bijection constructed by Foata and Han [6] on S_n serves the purpose of mapping $(inv, rl-min)$ to (sor, cyc) .

The bijection of Foata and Han is devised for the purpose of deriving the equidistribution of the six pairs of set-valued statistics $(\text{Cyc}, \text{Rmil})$, $(\text{Cyc}, \text{Lmap})$, $(\text{Rmil}, \text{Lmap})$, $(\text{Lmap}, \text{Rmil})$, $(\text{Lmap}, \text{Cyc})$ and $(\text{Rmil}, \text{Cyc})$ over S_n . It should be mentioned that the equidistribution of the three pairs of set-valued statistics $(\text{Lmap}, \text{Cyc})$, $(\text{Cyc}, \text{Lmap})$, $(\text{Lmap}, \text{Rmil})$ reduces to the equidistribution of the three pairs of integer-valued statistics $(\text{lr-max}, \text{cyc})$, $(\text{cyc}, \text{lr-max})$ and $(\text{lr-max}, \text{lr-min})$ established by Cori [4] by employing labeled Dyck paths and the Ossona de Mendez Rosenstiehl algorithm [5] on hypermaps.

As for Coxeter groups of type B , the sorting index can be analogously defined and it is Mahonian, see Petersen [10]. Let $\text{sor}_B, \text{inv}_B, \text{nmin}_B$ and l'_B denote the statistics on signed permutations analogous to $\text{sor}, \text{inv}, \text{nmin}$ and l' for permutations. Petersen obtained the following formulas for the joint distributions of $(\text{inv}_B, \text{nmin}_B)$ and (sor_B, l'_B) :

$$\sum_{\sigma \in B_n} q^{\text{sor}_B(\sigma)} t^{l'_B(\sigma)} = \sum_{\sigma \in B_n} q^{\text{inv}_B(\sigma)} t^{\text{nmin}_B(\sigma)} = \prod_{i=1}^n (1 + t[2i]_q - t).$$

We shall present a bijection on B_n which implies the equidistribution of $(\text{inv}_B, \text{Lmap}_B, \text{Rmil}_B)$ and $(\text{sor}_B, \text{Lmap}_B, \text{Cyc}_B)$ where $\text{Lmap}_B, \text{Rmil}_B$ and Cyc_B are set-valued statistics. In particular, this bijection transforms $(\text{inv}_B, \text{nmin}_B)$ to (sor_B, l'_B) . We introduce the A-code and the B-code of a signed permutation, which are analogous to the A-code and the B-code of a permutation. We show that the triple of statistics $(\text{inv}_B, \text{Lmap}_B, \text{Rmil}_B)$ of a signed permutation can be computed from its A-code whereas the triple of statistics $(\text{sor}_B, \text{Lmap}_B, \text{Cyc}_B)$ can be computed from its B-code. To be more specific, let σ be a signed permutation in B_n with A-code c . Let σ' be the signed permutation in B_n with B-code c . Then the triple of statistics $(\text{inv}_B, \text{Lmap}_B, \text{Rmil}_B)$ of σ coincides with the triple of statistics $(\text{sor}_B, \text{Lmap}_B, \text{Cyc}_B)$ of σ' . We also show that the six pairs of set-valued statistics $(\text{Cyc}_B, \text{Rmil}_B)$, $(\text{Cyc}_B, \text{Lmap}_B)$, $(\text{Rmil}_B, \text{Lmap}_B)$, $(\text{Lmap}_B, \text{Rmil}_B)$, $(\text{Lmap}_B, \text{Cyc}_B)$ and $(\text{Rmil}_B, \text{Cyc}_B)$ are equidistributed over B_n . As a consequence, we see that the four pairs of statistics (sor_B, l'_B) , $(\text{inv}_B, \text{nmin}_B)$, $(\text{inv}_B, \text{nmax}_B)$ and $(\text{sor}_B, \text{nmax}_B)$ are equidistributed over B_n .

For Coxeter groups of type D , let sor_D and inv_D denote the statistics analogous to sor and inv . Let D_n denote the subgroup of B_n consisting of all signed permutations with an even number of minus signs. In this case, Petersen has shown that sor_D and inv_D have the same generating function, that is,

$$\sum_{\sigma \in D_n} q^{\text{sor}_D(\sigma)} = \sum_{\sigma \in D_n} q^{\text{inv}_D(\sigma)} = [n]_q \prod_{r=1}^{n-1} [2r]_q.$$

We shall introduce two statistics nmin_D and $\tilde{l}'_D$ analogous to nmin and l' , and we shall construct a bijection in order to show that the pairs of statistics $(\text{inv}_D, \text{nmin}_D)$ and $(\text{sor}_D, \tilde{l}'_D)$ are equidistributed over D_n . Moreover, we prove that the bivariate generating

functions for $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$ are both equal to

$$D_n(q, t) = \prod_{r=1}^{n-1} (1 + q^r t + qt \cdot [2r]_q) .$$

2 The bijection of Foata and Han

In this section, we give a brief description of Foata and Han's bijection [6] on permutations. Then we shall show that this bijection indeed transforms $(inv, rl-min)$ to (sor, cyc) .

The group of permutations of $[n]$ is also known as a Coxeter group of type A . The *length* of a permutation $\sigma \in S_n$, denoted by $l(\sigma)$, is defined to be the minimal number of adjacent transpositions needed to express σ . It is not difficult to see that $inv(\sigma) = l(\sigma)$.

We adopt the notation of Foata and Han [6]. They have investigated several set-valued statistics which are defined as follows. Given a permutation $\sigma \in S_n$, it can be decomposed as a product of disjoint cycles whose minimum elements are $c_1, c_2, \dots, c_r$. Define $\text{Cyc } \sigma$ to be the set

$$\text{Cyc } \sigma = \{c_1, c_2, \dots, c_r\}.$$

Let $\omega = x_1 x_2 \cdots x_n$ be a word in which the letters are positive integers. The left to right maximum place set of ω , denoted by $\text{Lmap } \omega$, is the set of all places i such that $x_j < x_i$ for all $j < i$, while the right to left minimum letter set of ω , denoted by $\text{Rmil } \omega$, is the set of all letters x_i such that $x_j > x_i$ for all $j > i$. For a permutation σ of $[n]$, recall that $lr-max(\sigma)$ is the number of left-to-right maxima of σ , $rl-min(\sigma)$ is the number of right-to-left minima of σ , and $cyc(\sigma)$ is the number of cycles of σ . It is easy to see that the cardinalities of $\text{Lmap } \sigma$, $\text{Rmil } \sigma$ and $\text{Cyc } \sigma$ reduce to $lr-max(\sigma)$, $rl-min(\sigma)$ and $cyc(\sigma)$, respectively.

The Lehmer code [9] of a permutation $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n$ of $[n]$ is defined to be the sequence $\text{Leh } \sigma = (a_1, a_2, \dots, a_n)$, where

$$a_i = |\{j \mid 1 \leq j \leq i, \sigma_j \leq \sigma_i\}|.$$

Let SE_n denote the set of integer sequences $(a_1, a_2, \dots, a_n)$ such that $1 \leq a_i \leq i$ for all i . Then $\text{Leh}: S_n \longrightarrow \text{SE}_n$ is a bijection. Foata and Han [6] defined the A-code of a permutation σ to be a sequence

$$\text{A-code } \sigma = \text{Leh } \mathbf{i}\sigma$$

where $\mathbf{i}: \sigma \mapsto \sigma^{-1}$ denotes the inverse operation on S_n with respect to product of permutations. For example, for $\sigma = 31524$, then $\mathbf{i}\sigma = 24153$. Here a permutation $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n \in S_n$ standards for a one-to-one function on $[n]$ which maps i to σ_i for $1 \leq i \leq n$. We multiply permutations from right to left, that is, for $\pi, \sigma \in S_n$, we have $\pi\sigma(i) = \pi(\sigma(i))$ for $1 \leq i \leq n$.

For an integer sequence $a = (a_1, a_2, \dots, a_n) \in \text{SE}_n$, define $\text{Max } a$ to be the set $\{i \mid a_i = i\}$. Given a permutation $\sigma \in S_n$, Foata and Han [6] have shown that the A-code leads to a bijection from S_n to SE_n and the two set-valued statistics Rmil and Lmap of σ are determined by its A-code, that is,

$$\text{Rmil } \sigma = \text{Max (A-code } \sigma), \quad (2.1)$$

$$\text{Lmap } \sigma = \text{Rmil (A-code } \sigma). \quad (2.2)$$

Following the notation in [6], we rewrite (2.1) and (2.2) as

$$(\text{Rmil}, \text{Lmap}) \sigma = (\text{Max}, \text{Rmil}) \text{ A-code } \sigma. \quad (2.3)$$

Given a permutation $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n \in S_n$, the B-code can be defined as follows. For $1 \leq i \leq n$, let k_i be the smallest integer $k \geq 1$ such that $(\sigma^{-k})(i) \leq i$, where σ is considered as a bijective function on $[n]$. Then $b_i = (\sigma^{-k_i})(i)$. In fact, the B-code of a permutation can be easily determined by the cycle decomposition. To compute b_i , we assume that i appears in a cycle C . If i is the smallest element of C , then we set $b_i = i$. Otherwise, we choose b_i to be the element j of C such that $j < i$ and j is the closest to i . Notice that C is viewed as a directed cycle and the distance from j to i is meant to be the number of steps to reach i from j along the cycle. For example, let $\sigma = 24513$. Using the cycle decomposition $\sigma = (124)(35)$, we get the B-code $(1, 1, 3, 2, 3)$.

Foata and Han have shown that the B-code is a bijection from S_n to SE_n and the pair of set-valued statistics $(\text{Cyc}, \text{Lmap})$ of σ can be determined by the B-code of σ , that is,

$$(\text{Cyc}, \text{Lmap}) \sigma = (\text{Max}, \text{Rmil}) \text{ B-code } \sigma. \quad (2.4)$$

Combining the A-code and the B-code, Foata and Han [6] found a bijection ϕ on S_n as given by

$$\phi = (\text{B-code})^{-1} \circ \text{A-code}.$$

The bijection ϕ implies the following equidistributions.

Theorem 2.1 (Foata and Han [6]) *The six pairs of set-valued statistics $(\text{Cyc}, \text{Rmil})$, $(\text{Cyc}, \text{Lmap})$, $(\text{Rmil}, \text{Lmap})$, $(\text{Lmap}, \text{Rmil})$, $(\text{Lmap}, \text{Cyc})$, $(\text{Rmil}, \text{Cyc})$ are equidistributed over S_n :*

$$\begin{array}{ccccccc} S_n & \xrightarrow{\mathbf{i}} & S_n & \xrightarrow{\phi^{-1}} & S_n & \xrightarrow{\mathbf{i}} & S_n & \xrightarrow{\phi} & S_n & \xrightarrow{\mathbf{i}} & S_n \\ \left(\begin{smallmatrix} \text{Cyc} \\ \text{Rmil} \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Cyc} \\ \text{Lmap} \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Rmil} \\ \text{Lmap} \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Lmap} \\ \text{Rmil} \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Lmap} \\ \text{Cyc} \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Rmil} \\ \text{Cyc} \end{smallmatrix} \right). \end{array}$$

We now turn to the sorting index. Petersen has shown that the pairs of statistics (sor, cyc) and $(\text{inv}, \text{rl-min})$ have the same joint distribution over permutations and asked for a combinatorial interpretation of this fact. We shall show that the map ϕ transforms the pair of statistics $(\text{inv}, \text{rl-min})$ of a permutation σ to the pair of statistics (sor, cyc) of the permutation $\phi(\sigma)$. The following lemma shows that the pair of statistics $(\text{inv}, \text{rl-min})$ of σ can be computed from the A-code of σ .

Lemma 2.2 *Let σ be a permutation in S_n with A-code $a = (a_1, a_2, \dots, a_n)$. Then we have*

$$inv(\sigma) = \sum_{i=1}^n (i - a_i), \quad (2.5)$$

and

$$rl-min(\sigma) = |\text{Max } a|. \quad (2.6)$$

Proof. By the definition of the A-code, we find

$$inv(\sigma) = \binom{n}{2} - \sum_{i=1}^n (a_i - 1),$$

which can be rewritten as

$$\sum_{i=1}^n (i - a_i).$$

From (2.3) it follows that $rl-min(\sigma) = |\text{Rmil } \sigma| = |\text{Max } a|$, as desired. ■

The following lemma shows that the pair of statistics (sor, cyc) of σ can be recovered from the B-code.

Lemma 2.3 *Let σ be a permutation in S_n with B-code $b = (b_1, b_2, \dots, b_n)$. Then we have*

$$sor(\sigma) = \sum_{i=1}^n (i - b_i), \quad (2.7)$$

and

$$cyc(\sigma) = |\text{Max } b|. \quad (2.8)$$

Proof. Let us examine the algorithm of Foata and Han to recover a permutation σ from its B-code $b = (b_1, b_2, \dots, b_n) \in \text{SE}_n$. Start with the identity permutation $\sigma^{(0)} = 12 \cdots n$. For $1 \leq i \leq n$, the permutation $\sigma^{(i)}$ is obtained by exchanging i and the letter at the b_i -th place in $\sigma^{(i-1)}$. Notice that it may happen that $i = b_i$. Then the resulting permutation $\sigma^{(n)}$ is precisely the permutation with B-code b , that is, $\sigma = \sigma^{(n)}$. So we may write $\sigma^{(i)} = \sigma^{(i-1)}(b_i, i)$, where (b_i, i) is called a transposition even when $b_i = i$. Thus we obtain a decomposition of σ into transpositions

$$\sigma = (b_1, 1)(b_2, 2) \cdots (b_n, n).$$

Then by the definition of the sorting index, we see that

$$sor(\sigma) = \sum_{i=1}^n (i - b_i).$$

It follows from (2.4) that $cyc(\sigma) = |\text{Cyc } \sigma| = |\text{Max } b|$. This completes the proof. ■

Combining Lemma 2.2 and Lemma 2.3, we conclude that the bijection $\phi = (\text{B-code})^{-1} \circ \text{A-code}$ transforms $(inv, rl\text{-}min)$ to (sor, cyc) , that is, for any $\sigma \in S_n$,

$$(inv, rl\text{-}min) \sigma = (sor, cyc) \phi(\sigma).$$

By Theorem 2.1, the bijection ϕ preserves the set-valued statistic Lmap . Since

$$lr\text{-}max(\sigma) = |\text{Lmap } \sigma|,$$

ϕ preserves the statistic $lr\text{-}max$. Observing that

$$rl\text{-}min(\sigma) = lr\text{-}max(\mathbf{i}\sigma),$$

we arrive at the following equidistributions.

Theorem 2.4 *The four pairs of statistics (sor, cyc) , $(inv, rl\text{-}min)$, $(inv, lr\text{-}max)$ and $(sor, lr\text{-}max)$ are equidistributed over S_n :*

$$\begin{array}{ccccccc} S_n & \xrightarrow{\phi^{-1}} & S_n & \xrightarrow{\mathbf{i}} & S_n & \xrightarrow{\phi} & S_n \\ \left(\begin{smallmatrix} sor \\ cyc \end{smallmatrix} \right) & & \left(\begin{smallmatrix} inv \\ rl\text{-}min \end{smallmatrix} \right) & & \left(\begin{smallmatrix} inv \\ lr\text{-}max \end{smallmatrix} \right) & & \left(\begin{smallmatrix} sor \\ lr\text{-}max \end{smallmatrix} \right). \end{array}$$

3 A bijection on signed permutations

In this section, we construct a bijection which serves as a combinatorial interpretation of the equidistribution of the pairs of statistics $(inv_B, nmin_B)$ and (sor_B, l'_B) over signed permutations. In fact, this bijection implies the equidistribution of $(inv_B, \text{Lmap}_B, \text{Rmil}_B)$ and $(sor_B, \text{Lmap}_B, \text{Cyc}_B)$ over B_n . Moreover, we show that the six pairs of set-valued statistics $(\text{Cyc}_B, \text{Rmil}_B)$, $(\text{Cyc}_B, \text{Lmap}_B)$, $(\text{Rmil}_B, \text{Lmap}_B)$, $(\text{Lmap}_B, \text{Rmil}_B)$, $(\text{Lmap}_B, \text{Cyc}_B)$ and $(\text{Rmil}_B, \text{Cyc}_B)$ are equidistributed over B_n .

Let us recall some definitions. The hyperoctahedral group B_n is the group of bijections σ on $\{1, 2, \dots, n, \bar{1}, \bar{2}, \dots, \bar{n}\}$ such that $\sigma(\bar{i}) = \overline{\sigma(i)}$ for $i = 1, 2, \dots, n$, where $\bar{i}$ denotes $-i$. Clearly, one can represent an element $\sigma \in B_n$ by a signed permutation $a_1 a_2 \cdots a_n$ of $[n]$, that is, a permutation of $[n]$ with some elements associated with the minus sign.

The group B_n has the following Coxeter generators

$$S^B = \{(\bar{1}, 1), (1, 2), (2, 3), \dots, (n-1, n)\}.$$

The set of reflections of B_n is

$$T^B = \{(i, j) : 1 \leq i < j \leq n\} \cup \{(\bar{i}, j) : 1 \leq i \leq j \leq n\},$$

where the transposition (i, j) means to exchange i and j and exchange $\bar{i}$ with $\bar{j}$ provided that $i \neq \bar{j}$, and $(\bar{i}, i)$ means to exchange i and $\bar{i}$. For $\sigma \in B_n$, let $N(\sigma)$ denote the number of negative elements in the signed permutation notation.

As for permutations, Petersen [10] defined the sorting index for a signed permutation. Let σ be a signed permutation in B_n . By using the straight selection sort algorithm [8] of type B , Petersen has shown that σ has a unique factorization into a product of signed transpositions in T^B :

$$\sigma = (i_1, j_1)(i_2, j_2) \cdots (i_m, j_m), \quad (3.1)$$

where $0 < j_1 < j_2 < \cdots < j_m \leq n$. Then the sorting index of σ is defined by

$$sor_B(\sigma) = \sum_{r=1}^m (j_r - i_r - \chi(i_r < 0)).$$

For example, let $\sigma = 5\bar{4}\bar{3}1\bar{2}$. Then we have

$$\sigma = (\bar{1}, 2)(\bar{3}, 3)(\bar{2}, 4)(1, 5)$$

and $sor_B(\sigma) = 2 - (-1) - 1 + 3 - (-3) - 1 + 4 - (-2) - 1 + 5 - 1 = 16$.

For a signed permutation $\sigma \in B_n$, the length of σ , denoted $l_B(\sigma)$, is defined to be the minimal number of transpositions in S^B needed to express σ , see [1]. The reflection length of σ , denoted $l'_B(\sigma)$, is the minimal number of transpositions in T^B needed to express σ . The type B inversion number of σ , denoted $inv_B(\sigma)$, also denoted $finv$ in [7], is defined as

$$inv_B(\sigma) = |\{(i, j) : 1 \leq i < j \leq n, \sigma_i > \sigma_j\}| + |\{(i, j) : 1 \leq i \leq j \leq n, \bar{\sigma}_i > \sigma_j\}|.$$

Like the case of type A , we have $inv_B(\sigma) = l_B(\sigma)$, see [1, Section 8.1].

Recall that for a permutation $\pi \in S_n$, we have $l'(\pi) = n - cyc(\pi)$. Similarly, the reflection length of a signed permutation can be determined from its cycle decomposition. A signed permutation σ can be expressed as a product of disjoint signed cycles, see, Brenti [2], Chen and Stanley [3]. For example, let $\sigma = \bar{6}\bar{7}4\bar{3}51\bar{2}$. Then σ can be written as $\sigma = (1\ \bar{6})(5)(\bar{7}\ \bar{2})(4\ \bar{3})$. A signed cycle is said to be balanced if it contains an even number of minus signs, see [3]. Let $cyc_B(\sigma)$ denote the number of balanced cycles of σ . It is not difficult to see that $l'_B(\sigma) = n - cyc_B(\sigma)$.

We introduce some set-valued statistics for signed permutations which are analogous to those for permutations. For a signed permutation σ , let $C_1, C_2, \dots, C_r$ be the balanced signed cycles of σ . Let c_i be the smallest absolute value of elements of C_i . Define Cyc_B to be the set $\{c_1, c_2, \dots, c_r\}$.

Let $\omega = \omega_1\omega_2 \cdots \omega_n$ be a word of length n , where ω_i is an integer. The left to right maximum place set of ω , denoted $Lmap_B \omega$, and the right to left minimum letter set of ω , denoted $Rmil_B \omega$, are defined as follows,

$$Lmap_B \omega = \{i \mid \omega_i > |\omega_j| \text{ for any } j < i\},$$

$$\text{Rmil}_B \omega = \{\omega_i \mid 0 < \omega_i < |\omega_j| \text{ for any } j > i\}.$$

When σ is a signed permutation, the cardinality of $\text{Lmap}_B \sigma$ is denoted by $lr\text{-}max_B(\sigma)$ and the cardinality of $\text{Rmil}_B \sigma$ is denoted by $rl\text{-}min_B(\sigma)$. Let

$$nmin_B(\sigma) = |\{i : \sigma_i > |\sigma_j| \text{ for some } j > i\}| + N(\sigma)$$

and

$$nmax_B(\sigma) = |\{i : 0 < \sigma_i < |\sigma_j| \text{ for some } j < i\}| + N(\sigma).$$

Evidently, $nmin_B(\sigma) = n - rl\text{-}min_B(\sigma)$ and $nmax_B(\sigma) = n - lr\text{-}max_B(\sigma)$.

The following theorem is due to Petersen [10].

Theorem 3.1 *The pairs of statistics $(inv_B, nmin_B)$ and (sor_B, l'_B) are equidistributed over B_n :*

$$\sum_{\sigma \in B_n} q^{sor_B(\sigma)} t^{l'_B(\sigma)} = \sum_{\sigma \in B_n} q^{inv_B(\sigma)} t^{nmin_B(\sigma)}.$$

Petersen presented two different factorizations of the diagonal sum $\sum_{\sigma \in B_n} \sigma$ and showed that the two sides of the above equation are both equal to

$$B_n(q, t) = \prod_{i=1}^n (1 + t[2i]_q - t).$$

We shall construct a bijection $\psi: B_n \longrightarrow B_n$ which transforms $(inv_B, \text{Lmap}_B, \text{Rmil}_B)$ to $(sor_B, \text{Lmap}_B, \text{Cyc}_B)$. This bijection can be described in terms of two codes, the A-code and the B-code for signed permutations. For a signed permutation $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n \in B_n$, let $\mathbf{i}: \sigma \mapsto \sigma^{-1}$ denote the inverse operation on B_n with respect to product of signed permutations. We define the Lehmer code of the signed permutation σ to be the integer sequence $\text{Leh } \sigma = (a_1, a_2, \dots, a_n)$, where for each i ,

$$a_i = \text{sign } \sigma_i \cdot |\{j \mid 1 \leq j \leq i, |\sigma_j| \leq |\sigma_i|\}|.$$

Then the A-code of a signed permutation σ is defined to be an integer sequence

$$\text{A-code } \sigma = \text{Leh } \mathbf{i}\sigma.$$

Let SE_n^B be the set of integer sequences $(a_1, a_2, \dots, a_n)$ such that $a_i \in [-i, i] \setminus \{0\}$. For an integer sequence $a = (a_1, a_2, \dots, a_n) \in \text{SE}_n^B$, $\text{Max } a$ stands for the set $\{i \mid a_i = i\}$.

The following proposition shows that the two set-valued statistics Rmil_B and Lmap_B for a signed permutation σ can be recovered from the Lehmer code of σ . The proof is straightforward, and hence it is omitted.

Proposition 3.2 *Leh: $B_n \longrightarrow \text{SE}_n^{\text{B}}$ is a bijection and for each $\sigma \in B_n$, we have*

$$\text{Rmil}_{\text{B}} \text{ Leh } \sigma = \text{Rmil}_{\text{B}} \sigma, \quad (3.2)$$

and

$$\text{Max Leh } \sigma = \text{Lmap}_{\text{B}} \sigma. \quad (3.3)$$

For example, let $\sigma = 5 \bar{7} 1 \bar{4} 9 \bar{2} \bar{6} 3 8$. Then we have

$$\text{Leh } \sigma = (1, -2, 1, -2, 5, -2, -5, 3, 8)$$

and

$$\text{Rmil}_{\text{B}} \text{ Leh } \sigma = \text{Rmil}_{\text{B}} \sigma = \{1, 3, 8\},$$

$$\text{Max Leh } \sigma = \text{Lmap}_{\text{B}} \sigma = \{1, 5\}.$$

The above proposition implies that the A-code is a bijection from B_n to SE_n^{B} . It is easy to see that $\text{Rmil}_{\text{B}} \mathbf{i}\sigma = \text{Lmap}_{\text{B}} \sigma$ and $\text{Rmil}_{\text{B}} \sigma = \text{Lmap}_{\text{B}} \mathbf{i}\sigma$. So we are led to the following theorem which shows that the two set-valued statistics Rmil_{B} and Lmap_{B} for a signed permutation σ can be determined by the A-code of σ .

Theorem 3.3 *For any $\sigma \in B_n$, we have*

$$(\text{Rmil}_{\text{B}}, \text{Lmap}_{\text{B}}) \sigma = (\text{Max}, \text{Rmil}_{\text{B}}) \text{ A-code } \sigma. \quad (3.4)$$

Next we define the B-code for a signed permutation. Let $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n \in B_n$. For $1 \leq i \leq n$, let k_i be the smallest integer $k \geq 1$ such that $|\sigma^{-k}(i)| \leq i$. We define the B-code of σ to be the integer sequence $(b_1, b_2, \dots, b_n)$ with $b_i = (\sigma^{-k_i})(i)$. For example, the B-code of the signed permutation $\sigma = 3 \bar{1} \bar{6} \bar{5} 4 2$ is $(1, -1, 1, -4, -4, -3)$.

The B-code of a signed permutation can be also defined recursively as follows. First, the B-codes of the two signed permutations of B_1 are defined as B-code $1 = (1)$ and B-code $\bar{1} = (-1)$. For $n \geq 2$, we write a signed permutation $\sigma \in B_n$ as a product of disjoint signed cycles. There are two cases.

- Case 1. Assume that n has a positive sign in σ or $\sigma_n = \bar{n}$. Let $\sigma' \in B_{n-1}$ be the signed permutation obtained from σ by deleting n (or $\bar{n}$) in its cycle decomposition. Here if n (or $\bar{n}$) is in a cycle of length 1, we just delete this cycle. Let $b' = (b_1, b_2, \dots, b_{n-1})$ be the B-code of σ' . Then we define the B-code of σ to be $b = (b_1, b_2, \dots, b_{n-1}, \sigma^{-1}(n))$.
- Case 2. Assume that n has a minus sign in σ and $\sigma_n \neq \bar{n}$. Changing the sign of σ_n and deleting $\bar{n}$ in the cycle decomposition of σ , we obtain a signed permutation in B_{n-1} , denoted by σ' . Let $b' = (b_1, b_2, \dots, b_{n-1})$ be the B-code of σ' . Then we define the B-code of σ to be $b = (b_1, b_2, \dots, b_{n-1}, \sigma^{-1}(n))$.

The following theorem shows that the set-valued statistics Lmap_B and Cyc_B of a signed permutation can be computed from the B-code.

Theorem 3.4 *The B-code is a bijection from B_n to SE_n^B . Furthermore, for any $\sigma \in B_n$, we have*

$$(\text{Cyc}_B, \text{Lmap}_B) \sigma = (\text{Max}, \text{Rmil}_B) \text{ B-code } \sigma. \quad (3.5)$$

Proof. From the recursive definition, it is readily seen that the B-code is a bijection from B_n to SE_n^B . We shall use induction on n to prove (3.5). Clearly, the statement holds for $n = 1$. Assume that (3.5) holds for $n - 1$, where $n \geq 2$. Let $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n$ be a signed permutation of B_n with B-code b . Assume that σ' is the signed permutation of B_{n-1} given in the recursive definition of the B-code. Let $b' = (b_1, b_2, \dots, b_{n-1})$ be the B-code of σ' .

Now we claim that $\text{Cyc}_B \sigma = \text{Max } b$. There are two cases according to the sign of n in σ .

First, we consider the case when n has a positive sign in σ . If $\sigma_n \neq n$, let $t = \sigma^{-1}(n)$. Since σ' is obtained from σ by deleting n in its cycle form, the B-code of σ is $b = (b_1, b_2, \dots, b_{n-1}, t)$. Since $0 < t < n$, we have $\text{Cyc}_B \sigma = \text{Cyc}_B \sigma'$ and $\text{Max } b' = \text{Max } b$. By the induction hypothesis, $\text{Cyc}_B \sigma' = \text{Max } b'$. Hence $\text{Cyc}_B \sigma = \text{Max } b$. If $\sigma_n = n$, it can be easily checked that

$$\text{Cyc}_B \sigma = \text{Cyc}_B \sigma' \cup \{n\} = \text{Max } b' \cup \{n\} = \text{Max } b.$$

Then we consider the case when n has a minus sign in σ . If $\sigma_n = \bar{n}$, it is easy to see that

$$\text{Cyc}_B \sigma = \text{Cyc}_B \sigma' = \text{Max } b' = \text{Max } b.$$

If $\sigma_n \neq \bar{n}$, let $t = \sigma^{-1}(n)$. Since n has a minus sign in σ , we have $t < 0$. Since $b' = (b_1, b_2, \dots, b_{n-1})$ is the B-code of σ' , we find that the B-code of σ is $b = (b_1, b_2, \dots, b_{n-1}, t)$. Since $-n < t < 0$, we have $\text{Cyc}_B \sigma = \text{Cyc}_B \sigma'$ and $\text{Max } b' = \text{Max } b$. By the induction hypothesis, we get $\text{Cyc}_B \sigma' = \text{Max } b'$. Thus we obtain $\text{Cyc}_B \sigma = \text{Max } b$.

We now turn to the proof of the relation $\text{Lmap}_B \sigma = \text{Rmil}_B b$. There are four cases.

Case 1: $\sigma_n = n - 1$. By the recursive definition of the B-code, we express σ and σ' in the one-line notation as follows. For convenience, we display the identity permutation on the top,

$$\begin{array}{ccccccc} 1 & \cdots & |\sigma^{-1}(n)| & \cdots & n-1 & n \\ \sigma = & \sigma_1 & \cdots & v \cdot n & \cdots & \sigma_{n-1} & n-1 \\ \sigma' = & \sigma_1 & \cdots & v \cdot (n-1) & \cdots & \sigma_{n-1}. \end{array}$$

Here $v = 1$ if n has a positive sign in σ and $v = -1$ if n has a minus sign in σ . It can be readily seen that $\text{Lmap}_B \sigma = \text{Lmap}_B \sigma'$. Since $b' = (b_1, b_2, \dots, b_{n-1})$ is the B-code of σ' ,

we have $b_{n-1} = \sigma^{-1}(n)$ and the B-code of σ is $b = (b_1, b_2, \dots, b_{n-1}, \sigma^{-1}(n))$. It follows that $\text{Rmil}_B b = \text{Rmil}_B b'$. By the induction hypothesis, we get $\text{Lmap}_B \sigma' = \text{Rmil}_B b'$. Hence we deduce that $\text{Lmap}_B \sigma = \text{Rmil}_B b$.

Case 2: $\sigma_n = \overline{n-1}$. If n has a minus sign in σ , let t be the positive integer such that $\sigma_t = \bar{n}$. As in Case 1, we express σ and σ' as follows

$$\begin{array}{cccccc} 1 & \cdots & t & \cdots & n-1 & n \\ \sigma = & \sigma_1 & \cdots & \bar{n} & \cdots & \sigma_{n-1} & \overline{n-1} \\ \sigma' = & \sigma_1 & \cdots & n-1 & \cdots & \sigma_{n-1}. \end{array}$$

Clearly, $\text{Lmap}_B \sigma = \text{Lmap}_B \sigma' \setminus \{t\}$. Since $b' = (b_1, b_2, \dots, b_{n-1})$ is the B-code of σ' , we have $b_{n-1} = \sigma'^{-1}(n-1) = t$. From the recursive construction of the B-code, it follows that the B-code of σ is $b = (b_1, b_2, \dots, b_{n-1}, -t)$. This implies that $\text{Rmil}_B b = \text{Rmil}_B b' \setminus \{t\}$. By the induction hypothesis, we obtain $\text{Lmap}_B \sigma' = \text{Rmil}_B b'$. Therefore $\text{Lmap}_B \sigma = \text{Rmil}_B b$. If n has a positive sign in σ , let t be the positive integer such that $\sigma_t = n$. Then σ and σ' can be expressed as follows

$$\begin{array}{cccccc} 1 & \cdots & t & \cdots & n-1 & n \\ \sigma = & \sigma_1 & \cdots & n & \cdots & \sigma_{n-1} & \overline{n-1} \\ \sigma' = & \sigma_1 & \cdots & \overline{n-1} & \cdots & \sigma_{n-1}. \end{array}$$

In this case, we have $\text{Lmap}_B \sigma = \text{Lmap}_B \sigma' \cup \{t\}$. Since $b' = (b_1, b_2, \dots, b_{n-1})$ is the B-code of σ' , then $b_{n-1} = -t$ and the B-code of σ is $b = (b_1, b_2, \dots, b_{n-1}, t)$. It follows that $\text{Rmil}_B b = \text{Rmil}_B b' \cup \{t\}$. By the induction hypothesis, we deduce that $\text{Lmap}_B \sigma' = \text{Rmil}_B b'$. So we arrive at $\text{Lmap}_B \sigma = \text{Rmil}_B b$.

Case 3: $\sigma_n \neq n-1$, $\sigma_n \neq \overline{n-1}$ and $|\sigma^{-1}(n-1)| < |\sigma^{-1}(n)|$. If n has a positive sign in σ , let $\sigma_t = n$. Following the similar argument as in Case 2, we have $\text{Lmap}_B \sigma = \text{Lmap}_B \sigma' \cup \{t\}$ and $\text{Rmil}_B b = \text{Rmil}_B b' \cup \{t\}$. By the induction hypothesis, we deduce that $\text{Lmap}_B \sigma' = \text{Rmil}_B b'$. Hence $\text{Lmap}_B \sigma = \text{Rmil}_B b$. If n has a minus sign in σ , it can be verified that $\text{Lmap}_B \sigma = \text{Lmap}_B \sigma'$ and $\text{Rmil}_B b = \text{Rmil}_B b'$. Therefore, we obtain $\text{Lmap}_B \sigma = \text{Rmil}_B b$.

Case 4: $\sigma_n \neq n-1$, $\sigma_n \neq \overline{n-1}$ and $|\sigma^{-1}(n-1)| > |\sigma^{-1}(n)|$. If n has a positive sign in σ , let $\sigma_t = n$. We write σ and σ' as follows

$$\begin{array}{ccccccccc} 1 & \cdots & t & \cdots & |\sigma^{-1}(n-1)| & \cdots & n-1 & n \\ \sigma = & \sigma_1 & \cdots & n & \cdots & v_{n-1} \cdot (n-1) & \cdots & \sigma_{n-1} & \sigma_n \\ \sigma' = & \sigma_1 & \cdots & \sigma_n & \cdots & v_{n-1} \cdot (n-1) & \cdots & \sigma_{n-1}, \end{array}$$

where $v_{n-1} = 1$ if $n-1$ appears as an element in σ and $v_{n-1} = -1$ if $\overline{n-1}$ appears as an element in σ . It can be seen that

$$\text{Lmap}_B \sigma = (\text{Lmap}_B \sigma' \cap [1, t-1]) \cup \{t\}.$$

Since $b' = (b_1, b_2, \dots, b_{n-1})$ is the B-code of σ' , we have $b_{n-1} = \sigma^{-1}(n-1)$ and the B-code of σ is $b = (b_1, b_2, \dots, b_{n-1}, t)$. Hence we get

$$\text{Rmil}_B b = (\text{Rmil}_B b' \cap [1, t-1]) \cup \{t\}.$$

By the induction hypothesis, we obtain $\text{Lmap}_B \sigma' = \text{Rmil}_B b'$. Thus we get $\text{Lmap}_B \sigma = \text{Rmil}_B b$. If n has a minus sign in σ , it can be checked that $\text{Lmap}_B \sigma = \text{Lmap}_B \sigma' \cap [1, -\sigma^{-1}(n) - 1]$ and $\text{Rmil}_B b = \text{Rmil}_B b' \cap [1, -\sigma^{-1}(n) - 1]$. By the induction hypothesis, we conclude that $\text{Lmap}_B \sigma = \text{Rmil}_B b$. This completes the proof. $\blacksquare$

In fact, it can be shown that the pair of statistics $(\text{inv}_B, \text{nmin}_B)$ of a signed permutation σ can be recovered from its A-code and the pair of statistics (sor_B, l'_B) can be recovered from its B-code.

We now describe how to recover a signed permutation σ from its A-code $a = (a_1, a_2, \dots, a_n) \in \text{SE}_n^B$. It is essentially the same as the procedure to recover a permutation from the inversion code.

We start with the empty word $\sigma^{(0)}$, then it will take n steps to construct a signed permutation σ with A-code a . At the first step, if $a_1 = 1$, then set $\sigma^{(1)} = 1$. If $a_1 = -1$, then set $\sigma^{(1)} = \bar{1}$. For $1 < i \leq n$, assume that at step i , we have constructed a signed permutation $\sigma^{(i-1)} \in B_{i-1}$. If $|a_i| = 1$, the signed permutation $\sigma^{(i)}$ is obtained by inserting the element i with a sign of a_i before the first element of $\sigma^{(i-1)}$. If $|a_i| > 1$, then the signed permutation $\sigma^{(i)}$ is obtained from $\sigma^{(i-1)}$ by inserting the element i with a sign of a_i immediately after the $(|a_i| - 1)$ -th element in $\sigma^{(i-1)}$. Eventually, the signed permutation $\sigma^{(n)}$ is a signed permutation σ with A-code a . For example, $a = (1, 1, -3, -2, 3)$, then we have

$$\begin{aligned} \sigma^{(0)} &= \emptyset, \\ a_1 = 1, \quad \sigma^{(1)} &= 1, \\ a_2 = 1, \quad \sigma^{(2)} &= 2 \ 1, \\ a_3 = -3, \quad \sigma^{(3)} &= 2 \ 1 \ \bar{3}, \\ a_4 = -2, \quad \sigma^{(4)} &= 2 \ \bar{4} \ 1 \ \bar{3}, \\ a_5 = 3, \quad \sigma^{(5)} &= 2 \ \bar{4} \ 5 \ 1 \ \bar{3}. \end{aligned}$$

So the signed permutation $2 \ \bar{4} \ 5 \ 1 \ \bar{3}$ corresponds to the A-code $(1, 1, -3, -2, 3)$.

The relationship between a signed permutation σ and its B-code $b = (b_1, b_2, \dots, b_n)$ can be described as follows. Let σ' be the signed permutation obtained from σ as in the recursive construction of the B-code. So the B-code of σ' is $b' = (b_1, b_2, \dots, b_{n-1})$. If n has a positive sign in σ or $\sigma_n = \bar{n}$, then σ' is obtained from σ by deleting n in its cycle decomposition. Let (i, i) denote the identity permutation for any $1 \leq i \leq n$. Since $b_n = \sigma^{-1}(n)$, we have $\sigma = \sigma'(b_n, n)$. We note here that σ' is considered as a signed permutation of B_n which maps n to n . If n has a minus sign in σ and $\sigma_n \neq \bar{n}$, then σ' is obtained from σ by changing the sign of σ_n and deleting $\bar{n}$ in its cycle

decomposition. Since $b_n = \sigma^{-1}(n)$, it is readily seen that $\sigma = \sigma'(b_n, n)$. Again here σ' is considered as a signed permutation of B_n which maps n to n . Hence we obtain that $\sigma = (b_1, 1)(b_2, 2) \cdots (b_n, n)$.

The following lemma gives expressions of $inv_B(\sigma)$ and $nmin_B(\sigma)$ in terms of the A-code of σ .

Lemma 3.5 *For a signed permutation $\sigma \in B_n$ with A-code $a = (a_1, a_2, \dots, a_n)$, we have*

$$inv_B(\sigma) = \sum_{i=1}^n (i - a_i - \chi(a_i < 0)) \quad (3.6)$$

and

$$nmin_B(\sigma) = n - |\text{Max } a|. \quad (3.7)$$

Proof. Consider the procedure to recover a signed permutation from the A-code a . It is easily seen that after the i -th step, the type B inversion number increases by $i - a_i$ when $a_i > 0$ and by $i - a_i - 1$ when $a_i < 0$. Hence we have

$$inv_B(\sigma^{(i)}) - inv_B(\sigma^{(i-1)}) = i - a_i - \chi(a_i < 0).$$

Since $inv_B(\sigma^{(0)}) = 0$, we find

$$inv_B(\sigma) = \sum_{i=1}^n (i - a_i - \chi(a_i < 0)).$$

In view of (3.4), it is easy to see that $nmin_B(\sigma) = n - rl-min_B(\sigma) = n - |\text{Rmil}_B \sigma| = n - |\text{Max } a|$. This completes the proof. $\blacksquare$

The following lemma shows that $sor_B(\sigma)$ and $l'_B(\sigma)$ can be expressed in terms of the B-code of σ .

Lemma 3.6 *For a signed permutation $\sigma \in B_n$ with B-code $b = (b_1, b_2, \dots, b_n)$, we have*

$$sor_B(\sigma) = \sum_{i=1}^n (i - b_i - \chi(b_i < 0)) \quad (3.8)$$

and

$$l'_B(\sigma) = n - |\text{Max } b|. \quad (3.9)$$

Proof. Since $b = (b_1, b_2, \dots, b_n)$ is the B-code of σ , it has been shown that

$$\sigma = (b_1, 1)(b_2, 2) \cdots (b_n, n).$$

By the definition of the sorting index of σ , we see that

$$sor_B(\sigma) = \sum_{i=1}^n (i - b_i - \chi(b_i < 0)).$$

From (3.5) it follows that $l'_B(\sigma) = n - cyc_B(\sigma) = n - |\text{Cyc}_B \sigma| = n - |\text{Max } b|$. This completes the proof. $\blacksquare$

Combining Theorem 3.3, Theorem 3.4, Lemma 3.5 and Lemma 3.6, we obtain the equidistribution of $(inv_B, \text{Lmap}_B, \text{Rmil}_B)$ and $(sor_B, \text{Lmap}_B, \text{Cyc}_B)$ over B_n .

Theorem 3.7 *The map $\psi: B_n \longrightarrow B_n$ defined by $\psi = (\text{B-code})^{-1} \circ \text{A-code}$ is a bijection. For any $\sigma \in B_n$, we have*

$$(inv_B, \text{Lmap}_B, \text{Rmil}_B) \sigma = (sor_B, \text{Lmap}_B, \text{Cyc}_B) \psi(\sigma). \quad (3.10)$$

In particular,

$$(inv_B, nmin_B) \sigma = (sor_B, l'_B) \psi(\sigma). \quad (3.11)$$

Notice that $\text{Cyc}_B \sigma = \text{Cyc}_B \mathbf{i}\sigma$ and $\text{Lmap}_B \sigma = \text{Rmil}_B \mathbf{i}\sigma$. Thus Theorem 3.7 implies the following equidistributions which can be viewed as type B analogues of the equidistributions given in Theorem 2.1.

Theorem 3.8 *The six pairs of set-valued statistics $(\text{Cyc}_B, \text{Rmil}_B)$, $(\text{Cyc}_B, \text{Lmap}_B)$, $(\text{Rmil}_B, \text{Lmap}_B)$, $(\text{Lmap}_B, \text{Rmil}_B)$, $(\text{Lmap}_B, \text{Cyc}_B)$ and $(\text{Rmil}_B, \text{Cyc}_B)$ are equidistributed over B_n :*

$$\begin{array}{ccccccc} B_n & \xrightarrow{\mathbf{i}} & B_n & \xrightarrow{\psi^{-1}} & B_n & \xrightarrow{\mathbf{i}} & B_n & \xrightarrow{\psi} & B_n & \xrightarrow{\mathbf{i}} & B_n \\ \left(\begin{smallmatrix} \text{Cyc}_B \\ \text{Rmil}_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Cyc}_B \\ \text{Lmap}_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Rmil}_B \\ \text{Lmap}_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Lmap}_B \\ \text{Rmil}_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Lmap}_B \\ \text{Cyc}_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} \text{Rmil}_B \\ \text{Cyc}_B \end{smallmatrix} \right). \end{array}$$

The above theorem for set-valued statistics reduces to the following equidistributions of pairs of statistics of signed permutations. It is clear that $nmin_B(\sigma) = nmax_B(\mathbf{i}\sigma)$. Since the bijection ψ preserves Lmap_B , it is easy to see that ψ also preserves the statistic $nmax_B$. Hence we are led to the following assertion.

Corollary 3.9 *The four pairs of statistics (sor_B, l'_B) , $(inv_B, nmin_B)$, $(inv_B, nmax_B)$ and $(sor_B, nmax_B)$ are equidistributed over B_n :*

$$\begin{array}{ccccccc} B_n & \xrightarrow{\psi^{-1}} & B_n & \xrightarrow{\mathbf{i}} & B_n & \xrightarrow{\psi} & B_n \\ \left(\begin{smallmatrix} sor_B \\ l'_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} inv_B \\ nmin_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} inv_B \\ nmax_B \end{smallmatrix} \right) & & \left(\begin{smallmatrix} sor_B \\ nmax_B \end{smallmatrix} \right). \end{array}$$

4 A bijection on D_n

In this section, we define two statistics $nmin_D$ and $\tilde{l}_D$ for elements of a Coxeter group of type D and we construct a bijection to derive the equidistribution of the pairs of statistics $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}_D)$. This yields a refinement of Petersen's equidistribution of inv_D and sor_D .

The type D Coxeter group D_n is the subgroup of B_n consisting of signed permutations with an even number of minus signs in the signed permutation notation. As a set of generators for D_n , we take

$$S^D = \{(\bar{1}, 2), (1, 2), (2, 3), \dots, (n-1, n)\}.$$

For simplicity, let $s_i = (i, i+1)$ for $1 \leq i < n$ and $s_{\bar{1}} = (\bar{1}, 2)$. The set of reflections of D_n is

$$R^D = \{(i, j) : 1 \leq |i| < j \leq n\}.$$

For $\sigma = \sigma_1 \sigma_2 \cdots \sigma_n \in D_n$, the type D inversion number of σ is given by

$$inv_D(\sigma) = |\{(i, j) : 1 \leq i < j \leq n, \sigma_i > \sigma_j\}| + |\{(i, j) : 1 \leq i < j \leq n, \bar{\sigma}_i > \sigma_j\}|.$$

The length of σ , denoted $l_D(\sigma)$, is the minimal number of transpositions in S^D needed to express σ . It is known that $l_D(\sigma) = inv_D(\sigma)$, see [1, Section 8.2].

It is well-known that the generating function of l_D is

$$\sum_{\sigma \in D_n} q^{l_D(\sigma)} = [n]_q \prod_{r=1}^{n-1} [2r]_q, \quad (4.1)$$

see [1].

Recall that the set of reflections of B_n is

$$T^B = \{(i, j) : 1 \leq i < j \leq n\} \cup \{(\bar{i}, j) : 1 \leq i \leq j \leq n\}.$$

For $\sigma \in D_n$, it has a unique factorization into a product of signed transpositions in T^B :

$$\sigma = (i_1, j_1)(i_2, j_2) \cdots (i_k, j_k), \quad (4.2)$$

where $0 < j_1 < j_2 < \cdots < j_k \leq n$. Petersen defined the type D sorting index of σ as

$$sor_D(\sigma) = \sum_{r=1}^k (j_r - i_r - 2\chi(i_r < 0)).$$

It has been shown by Petersen that sor_D has the same generating function as inv_D .

Theorem 4.1 For $n \geq 4$,

$$\sum_{\sigma \in D_n} q^{sor_D(\sigma)} = [n]_q \prod_{r=1}^{n-1} [2r]_q. \quad (4.3)$$

Thus, sor_D is Mahonian.

Next we define two statistics $\tilde{l}'_D$ and $nmin_D$ for a signed permutation $\sigma \in D_n$. For $1 \leq |i| < j \leq n$, we adopt the notation t_{ij} for the transposition (i, j) . For $1 < i \leq n$, we define $t_{\bar{i}i} = (\bar{i}, i)(\bar{1}, 1)$. Then we set

$$T^D = \{t_{ij} : 1 \leq |i| < j \leq n\} \cup \{t_{\bar{i}i} : 1 < i \leq n\}.$$

We denote by $\tilde{l}'_D(\sigma)$ the minimal number of elements in T^D that are needed to express σ . Define the statistic $nmin_D$ as follows

$$nmin_D(\sigma) = |\{i : \sigma_i > |\sigma_j| \text{ for some } j > i\}| + N(\sigma \setminus \{\bar{1}\}),$$

where $N(\sigma \setminus \{\bar{1}\})$ is the number of minus signs associated with elements greater than 1 in the signed permutation notation of σ .

The following theorem is a refinement of the equidistribution of inv_D and sor_D . We shall give a combinatorial proof and an algebraic proof.

Theorem 4.2 For $n \geq 2$, the two pairs of statistics $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$ are equidistributed over D_n . Moreover, we have

$$\sum_{\sigma \in D_n} q^{inv_D(\sigma)} t^{nmin_D(\sigma)} = \prod_{r=1}^{n-1} (1 + q^r t + qt \cdot [2r]_q), \quad (4.4)$$

$$\sum_{\sigma \in D_n} q^{sor_D(\sigma)} t^{\tilde{l}'_D(\sigma)} = \prod_{r=1}^{n-1} (1 + q^r t + qt \cdot [2r]_q). \quad (4.5)$$

To give a combinatorial proof of the equidistribution of $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$ in Theorem 4.2, we introduce the co-sorting index sor'_D which turns out to be equivalent to the sorting index sor_D . To define the co-sorting index, we need the factorization of an element $\sigma \in D_n$ into elements in T^D . More precisely, similarly as (3.1), we can uniquely express $\sigma \in D_n$ as

$$\sigma = t_{i_1 j_1} t_{i_2 j_2} \cdots t_{i_m j_m},$$

where $1 < j_1 < j_2 < \cdots < j_m \leq n$. For example, let $\sigma = \bar{2} \bar{4} 5 \bar{1} \bar{3}$. Then we have $\sigma = t_{12} t_{\bar{3}3} t_{\bar{2}4} t_{35}$. Then the co-sorting index of σ is defined by

$$sor'_D(\sigma) = \sum_{r=1}^m (j_r - i_r - 2\chi(i_r < 0)).$$

Lemma 4.3 For any $\sigma \in D_n$, we have $\text{sor}_D(\sigma) = \text{sor}'_D(\sigma)$.

Proof. Write σ in the following form

$$\sigma = t_{i_1 j_1} t_{i_2 j_2} \cdots t_{i_m j_m}, \quad (4.6)$$

where $t_{i_1 j_1}, t_{i_2 j_2}, \dots, t_{i_m j_m} \in T^D$ and $1 < j_1 < j_2 < \cdots < j_m \leq n$. Since the co-sorting index of σ can be expressed in terms of the factorization (4.6), to prove the equivalence of the sorting index and the co-sorting index of σ , we wish to rewrite (4.6) as a product of transpositions in T^B from which the sorting index of σ can be determined.

In fact, it can be shown that σ can be written as a product of transpositions in T^B which is either of the form

$$(p_1, j_1)(p_2, j_2) \cdots (p_m, j_m), \quad (4.7)$$

or of the form

$$(\bar{1}, 1)(p_1, j_1)(p_2, j_2) \cdots (p_m, j_m), \quad (4.8)$$

where for $1 \leq k \leq m$,

$$p_k = \begin{cases} 1 \text{ or } \bar{1}, & \text{if } i_k = 1, \\ 1 \text{ or } \bar{1}, & \text{if } i_k = \bar{1}, \\ i_k, & \text{otherwise.} \end{cases} \quad (4.9)$$

To this end, we claim that for $1 \leq r \leq m$, $t_{i_r j_r} t_{i_{r+1} j_{r+1}} \cdots t_{i_m j_m}$ can be expressed as a product of transpositions in T^B which is either of the form

$$(p_r, j_r)(p_{r+1}, j_{r+1}) \cdots (p_m, j_m) \quad (4.10)$$

or of the form

$$(\bar{1}, 1)(p_r, j_r)(p_{r+1}, j_{r+1}) \cdots (p_m, j_m), \quad (4.11)$$

where p_k is given as in (4.9). Let us first consider the case $r = m$. In this case, if $i_m \neq \overline{j_m}$, then $t_{i_m j_m}$ equals (i_m, j_m) which is of the form (4.10). If $i_m = \overline{j_m}$, then $t_{i_m j_m}$ equals $(\bar{1}, 1)(i_m, j_m)$ which is of the form (4.11).

Assume the claim holds for r , where $1 < r \leq m$. We aim to show that it holds for $r - 1$. If $t_{i_r j_r} t_{i_{r+1} j_{r+1}} \cdots t_{i_m j_m}$ can be expressed in the form (4.10), then we have

$$t_{i_{r-1} j_{r-1}} t_{i_r j_r} \cdots t_{i_m j_m} = \begin{cases} (\bar{1}, 1)(i_{r-1}, j_{r-1})(p_r, j_r) \cdots (p_m, j_m), & \text{if } i_{r-1} = \overline{j_{r-1}}, \\ (i_{r-1}, j_{r-1})(p_r, j_r) \cdots (p_m, j_m), & \text{otherwise,} \end{cases}$$

which is either of the form (4.11) or of the form (4.10). We now assume that $t_{i_r j_r} t_{i_{r+1} j_{r+1}} \cdots t_{i_m j_m}$ can be expressed in the form (4.11). It follows that

$$t_{i_{r-1} j_{r-1}} t_{i_r j_r} \cdots t_{i_m j_m} = \begin{cases} (i_{r-1}, j_{r-1})(p_r, j_r) \cdots (p_m, j_m), & \text{if } i_{r-1} = \overline{j_{r-1}}, \\ (\bar{1}, 1)(\overline{i_{r-1}}, j_{r-1})(p_r, j_r) \cdots (p_m, j_m), & \text{if } i_{r-1} = 1 \text{ or } \bar{1}, \\ (\bar{1}, 1)(i_{r-1}, j_{r-1})(p_r, j_r) \cdots (p_m, j_m), & \text{otherwise,} \end{cases}$$

which is either of the form (4.10) or of the form (4.11). Thus we have verified that the claim holds for any $1 \leq r \leq m$.

Now we have shown that σ can be expressed as (4.7) or (4.8). Then the sorting index $sor_D(\sigma)$ can be determined by this factorization, namely,

$$sor_D(\sigma) = \sum_{r=1}^m (j_r - p_r - 2\chi(p_r < 0)).$$

By (4.9), we find that

$$j_r - p_r - 2\chi(p_r < 0) = j_r - i_r - 2\chi(i_r < 0)$$

for $1 \leq r \leq m$. In view of (4.6), we see that

$$sor'_D(\sigma) = \sum_{r=1}^m (j_r - i_r - 2\chi(i_r < 0)).$$

It follows that $sor_D(\sigma) = sor'_D(\sigma)$. This completes the proof. $\blacksquare$

To justify the equidistribution of $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$, we shall give a bijection which transforms $(inv_D, nmin_D)$ to $(sor_D, \tilde{l}'_D)$. The bijection will be described in terms of two codes, called the E-code and the F-code of an element of D_n . It will be shown that the pair of statistics $(inv_D, nmin_D)$ can be computed from the E-code whereas the pair of statistics $(sor_D, \tilde{l}'_D)$ can be computed from the F-code.

Given an element $\sigma \in D_n$, the E-code of σ is an integer sequence $e = (e_1, e_2, \dots, e_n)$ generated by the following procedure. We wish to construct a sequence of signed permutations $\sigma^{(n)}, \sigma^{(n-1)}, \dots, \sigma^{(1)}$ where $\sigma^{(i)} \in D_i$ for $1 \leq i \leq n$. First, we set $\sigma^{(n)} = \sigma$. For i from n to 2 , we construct $\sigma^{(i-1)}$ from $\sigma^{(i)}$. Consider the letter i in $\sigma^{(i)}$. If i has a positive sign in $\sigma^{(i)}$, then assume that i appears at the p -th position in $\sigma^{(i)}$. In this case, we set $e_i = p$ and let $\sigma^{(i-1)}$ be the signed permutation obtained from $\sigma^{(i)}$ by deleting the element i . If i has a minus sign in $\sigma^{(i)}$, then we assume that $\bar{i}$ appears at the p -th position in $\sigma^{(i)}$. We then set $e_i = -p$. Let σ' be the signed permutation obtained from $\sigma^{(i)}$ by deleting $\bar{i}$, and let $\sigma^{(i-1)}$ be the signed permutation obtained from σ' by changing the sign of the element at the first position. It can be seen that the resulting signed permutation $\sigma^{(1)}$ is the identity permutation 1 . Finally, we set $e_1 = 1$. For example, let $\sigma = 2\bar{4}51\bar{3}$. Then we have

$$\begin{aligned} \sigma^{(5)} &= 2\bar{4}\mathbf{5}1\bar{3}, & e_5 &= 3, \\ \sigma^{(4)} &= 2\bar{4}1\bar{3}, & e_4 &= -2, \\ \sigma^{(3)} &= \bar{2}1\bar{3}, & e_3 &= -3, \\ \sigma^{(2)} &= \mathbf{2}1, & e_2 &= 1, \\ \sigma^{(1)} &= 1, & e_1 &= 1. \end{aligned}$$

Hence the E-code of $\sigma = 2\bar{4}51\bar{3}$ is $(1, 1, -3, -2, 3)$.

It can be checked that the above procedure is reversible. In other words, one can recover an element $\sigma \in D_n$ from an E-code $e = (e_1, e_2, \dots, e_n)$. For $1 < r \leq n$, it is routine to verify that

$$\text{inv}_D(\sigma^{(r)}) - \text{inv}_D(\sigma^{(r-1)}) = r - e_r - 2\chi(e_r < 0) \quad (4.12)$$

and

$$\text{nmin}_D(\sigma^{(r)}) - \text{nmin}_D(\sigma^{(r-1)}) = 1 - \chi(e_r = r). \quad (4.13)$$

So we are led to the following formulas for $\text{inv}_D(\sigma)$ and $\text{nmin}_D(\sigma)$.

Proposition 4.4 *Given an element $\sigma \in D_n$, let $e = (e_1, e_2, \dots, e_n)$ be its E-code. Then we have*

$$\text{inv}_D(\sigma) = \sum_{r=1}^n (r - e_r - 2\chi(e_r < 0)) \quad (4.14)$$

and

$$\text{nmin}_D(\sigma) = n - \sum_{r=1}^n \chi(e_r = r). \quad (4.15)$$

We now define the F-code of an element $\sigma \in D_n$ as an integer sequence $f = (f_1, f_2, \dots, f_n)$ determined by the following procedure. To compute the F-code f , we will generate a sequence of signed permutations $\sigma^{(n)}, \sigma^{(n-1)}, \dots, \sigma^{(1)} \in D_n$. Let us begin with $\sigma^{(n)} = \sigma$. For i from n to 2 , we construct $\sigma^{(i-1)}$ from $\sigma^{(i)}$. Consider the letter i in $\sigma^{(i)}$. If i has a positive sign in $\sigma^{(i)}$, say $\sigma^{(i)}(p) = i$, then let $f_i = p$ and let $\sigma^{(i-1)}$ be the signed permutation obtained from $\sigma^{(i)}$ by exchanging the letter i and the letter at the i -th position. If i has a minus sign in $\sigma^{(i)}$ and $\sigma^{(i)}(i) = \bar{i}$, then let $f_i = -i$ and let $\sigma^{(i-1)}$ be the signed permutation obtained from $\sigma^{(i)}$ by changing both the signs of the element at the i -th position and the element at the first position. If i has a minus sign in $\sigma^{(i)}$ and $\sigma^{(i)}(i) \neq \bar{i}$, say $\sigma^{(i)}(p) = \bar{i}$, then let $f_i = -p$ and let $\sigma^{(i-1)} = \sigma^{(i)}(\bar{p}, i)$. It can be readily seen that the resulting signed permutation $\sigma^{(1)}$ is the identity permutation $1\,2\cdots n$. Finally, we set $f_1 = 1$. For example, let $\sigma = \bar{2}\,\bar{4}\,5\,\bar{1}\,\bar{3}$. Then we proceed as follows

$$\begin{aligned} \sigma^{(5)} &= \bar{2}\,\bar{4}\,\mathbf{5}\,\bar{1}\,\bar{3}, & f_5 &= 3, \\ \sigma^{(4)} &= \bar{2}\,\bar{4}\,\bar{3}\,\bar{1}\,5, & f_4 &= \bar{2}, \\ \sigma^{(3)} &= \bar{2}\,1\,\mathbf{\bar{3}}\,4\,5, & f_3 &= \bar{3}, \\ \sigma^{(2)} &= \mathbf{2}\,1\,3\,4\,5, & f_2 &= 1, \\ \sigma^{(1)} &= 1\,2\,3\,4\,5, & f_1 &= 1. \end{aligned}$$

Hence the F-code of $\sigma = \bar{2}\,\bar{4}\,5\,\bar{1}\,\bar{3}$ is $(1, 1, -3, -2, 3)$. It is easily seen that the above procedure is reversible. So we can recover σ from its F-code.

The following proposition gives expressions of sor_D and $\tilde{l}'_D(\sigma)$ in terms of the F-code.

Proposition 4.5 *Given an element $\sigma \in D_n$, let $f = (f_1, f_2, \dots, f_n)$ be its F-code. Then we have*

$$\text{sor}_D(\sigma) = \sum_{r=1}^n (r - f_r - 2\chi(f_r < 0)) \quad (4.16)$$

and

$$\tilde{l}'_D(\sigma) = n - \sum_{r=1}^n \chi(f_r = r). \quad (4.17)$$

Proof. For $1 \leq i \leq n$, we let t_{ii} denote the identity permutation. Examining the procedure to construct the F-code of σ , we see that for $1 < r \leq n$, we have

$$\sigma^{(r)} = \sigma^{(r-1)} t_{f_r r}. \quad (4.18)$$

It follows that

$$\sigma^{(r)} = t_{f_1 1} t_{f_2 2} \cdots t_{f_r r}. \quad (4.19)$$

By the definition of the co-sorting index, we find

$$\text{sor}'_D(\sigma^{(r)}) - \text{sor}'_D(\sigma^{(r-1)}) = r - f_r - 2\chi(f_r < 0). \quad (4.20)$$

Applying Lemma 4.3, we get

$$\text{sor}_D(\sigma^{(r)}) - \text{sor}_D(\sigma^{(r-1)}) = r - f_r - 2\chi(f_r < 0). \quad (4.21)$$

Summing (4.21) over r gives (4.16).

To prove (4.17), it suffices to show that

$$\tilde{l}'_D(\sigma^{(r)}) - \tilde{l}'_D(\sigma^{(r-1)}) = 1 - \chi(f_r = r) \quad (4.22)$$

for $1 < r \leq n$. If $f_r = r$, it is clear that $\sigma^{(r)} = \sigma^{(r-1)}$. So (4.22) holds in this case. If $f_r \neq r$, let $\tilde{l}'_D(\sigma^{(r)}) = l$. Then $\sigma^{(r)}$ can be decomposed as

$$\sigma^{(r)} = t_{i_1 j_1} t_{i_2 j_2} \cdots t_{i_l j_l} \quad (4.23)$$

where $t_{i_1 j_1}, t_{i_2 j_2}, \dots, t_{i_l j_l} \in T^D$. For $t = t_{ij} \in T^D$ and $1 < k \leq n$, we say that t fixes k if and only if $k \neq i, \bar{i}, j$ or $\bar{j}$ in the sense that if $k \neq i, \bar{i}, j$ or $\bar{j}$, then t_{ij} maps k to k when we consider t_{ij} as a map on $\{1, 2, \dots, n, \bar{1}, \bar{2}, \dots, \bar{n}\}$. It can be verified that for any $1 < k \leq n$ and $t_1, t_2 \in T^D$, there exist $t_3, t_4 \in T^D$ such that $t_1 t_2 = t_3 t_4$ and t_3 fixes k . Thus we can use (4.23) to derive an expression of $\sigma^{(r)}$ of the form

$$\sigma^{(r)} = t_{i'_1 j'_1} t_{i'_2 j'_2} \cdots t_{i'_l j'_l} \quad (4.24)$$

where $t_{i'_1 j'_1}, t_{i'_2 j'_2}, \dots, t_{i'_l j'_l} \in T^D$ and $t_{i'_p j'_p}$ fixes r for $1 \leq p \leq l-1$. Since $f_r \neq r$, it follows from (4.19) that $\sigma^{(r)}$ maps f_r to r . Hence we deduce that $t_{i'_l j'_l} = t_{f_r r}$. By (4.18) and (4.24), we get

$$t_{i'_1 j'_1} t_{i'_2 j'_2} \cdots t_{i'_{l-1} j'_{l-1}} = \sigma^{(r-1)}.$$

Hence we arrive at

$$\tilde{l}'(\sigma^{(r-1)}) \leq l - 1.$$

From (4.18), it is clear that

$$l \leq \tilde{l}'(\sigma^{(r-1)}) + 1,$$

so we conclude that

$$l = \tilde{l}'(\sigma^{(r-1)}) + 1. \quad (4.25)$$

This completes the proof of (4.17). $\blacksquare$

Combining Propositions 4.4 and 4.5, we obtain a bijection $\rho: D_n \rightarrow D_n$ which leads to the equidistribution of $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$. More precisely, the bijection ρ is given by

$$\rho = \text{F-code}^{-1} \circ \text{E-code}.$$

Then we arrive at the following theorem.

Theorem 4.6 *The bijection ρ transforms $(inv_D, nmin_D)$ to $(sor_D, \tilde{l}'_D)$, that is, for any $\sigma \in D_n$, we have*

$$(inv_D, nmin_D) \sigma = (sor_D, \tilde{l}'_D) \rho(\sigma). \quad (4.26)$$

We now present a proof of Theorem 4.2 based on two different factorizations of the diagonal sum $\sum_{\sigma \in D_n} \sigma$ in the group algebra $\mathbb{Z}[D_n]$. It turns out that the bivariate generating functions of $(inv_D, nmin_D)$ and $(sor_D, \tilde{l}'_D)$ are both equal to

$$D_n(q, t) = \prod_{r=1}^{n-1} (1 + q^r t + qt \cdot [2r]_q).$$

To derive the bivariate generating function of $(inv_D, nmin_D)$, we recall Petersen's factorization of the diagonal sum $\sum_{\sigma \in D_n} \sigma$. The elements $\Psi_1, \Psi_2, \dots, \Psi_{n-1}$ of the group algebra of D_n are recursively defined as follows. Recall that $s_i = (i, i+1)$ for $1 \leq i < n$ and $s_{\bar{1}} = (\bar{1}, 2)$. For $i = 1$, let

$$\Psi_1 = 1 + s_1 + s_{\bar{1}} + s_1 s_{\bar{1}}.$$

For $i \geq 2$, let

$$\Psi_i = 1 + s_i \Psi_{i-1} + s_i \cdots s_2 s_1 s_{\bar{1}} s_2 \cdots s_i.$$

Petersen found the following factorization.

Proposition 4.7 *For $n \geq 2$,*

$$\sum_{\sigma \in D_n} \sigma = \Psi_1 \Psi_2 \cdots \Psi_{n-1}.$$

For an element $\sigma \in D_n$, we define the weight of σ to be

$$\mu(\sigma) = q^{\text{inv}_D(\sigma)} t^{\text{nm}_{\text{in}_D}(\sigma)}.$$

As usual, the weight function is considered as a linear map on $\mathbb{Z}[D_n]$. It can be routinely checked that

$$\mu(\Psi_i) = 1 + tq^i + tq(1 + q + \cdots + q^{2i-1}) = 1 + tq^i + tq[2i]_q. \quad (4.27)$$

We are now ready to finish the proof of relation (4.4) concerning the bivariate generating function of $(\text{inv}_D, \text{nm}_{\text{in}_D})$.

Proof of (4.4) in Theorem 4.2. By Proposition 4.7 and formula (4.27), we see that (4.4) can be rewritten as

$$\mu(\Psi_1 \cdots \Psi_{n-1}) = \psi(\Psi_1) \cdots \psi(\Psi_{n-1}).$$

Notice that for $i \geq 1$ and $i+2 \leq k \leq n$, each term of Ψ_i fixes k . Here we say an element $\sigma \in D_n$ fixes k if and only if σ maps k to k . Thus Ψ_i can be considered as an element of $\mathbb{Z}[D_j]$ for $i < j < n$. Clearly, the weight function μ is also well-defined in this sense. Therefore we only need to show that

$$\mu(\Psi_1 \cdots \Psi_{n-2} \Psi_{n-1}) = \mu(\Psi_1 \cdots \Psi_{n-2}) \mu(\Psi_{n-1}).$$

It suffices to prove that

$$\mu(\sigma \cdot \Psi_{n-1}) = \mu(\sigma) \cdot \mu(\Psi_{n-1}) \quad (4.28)$$

for any $\sigma = \sigma_1 \cdots \sigma_{n-1} \in D_{n-1}$. Here σ is considered as an element of D_n which fixes n . It can be verified that

$$\begin{aligned} \sigma \cdot \Psi_{n-1} &= \sigma_1 \cdots \sigma_{n-1} n + \sigma_1 \cdots \sigma_{n-2} n \sigma_{n-1} + \cdots + \sigma_1 n \cdots \sigma_{n-1} + n \sigma_1 \cdots \sigma_{n-1} \\ &\quad + \bar{n} \bar{\sigma}_1 \cdots \sigma_{n-1} + \bar{\sigma}_1 \bar{n} \cdots \sigma_{n-1} + \cdots + \bar{\sigma}_1 \cdots \sigma_{n-1} \bar{n}. \end{aligned}$$

Then we have

$$\begin{aligned} \mu(\sigma \cdot \Psi_{n-1}) &= \mu(\sigma_1 \cdots \sigma_{n-1} n) + \mu(\sigma_1 \cdots \sigma_{n-2} n \sigma_{n-1}) + \cdots + \mu(\sigma_1 n \cdots \sigma_{n-1}) + \mu(n \sigma_1 \cdots \sigma_{n-1}) \\ &\quad + \mu(\bar{n} \bar{\sigma}_1 \cdots \sigma_{n-1}) + \mu(\bar{\sigma}_1 \bar{n} \cdots \sigma_{n-1}) + \cdots + \mu(\bar{\sigma}_1 \cdots \sigma_{n-1} \bar{n}) \\ &= \mu(\sigma) + qt \mu(\sigma) + \cdots + q^{n-2} t \mu(\sigma) + q^{n-1} t \mu(\sigma) \\ &\quad + q^{n-1} t \mu(\sigma) + q^n t \mu(\sigma) + \cdots + q^{2n-2} t \mu(\sigma) \\ &= (1 + tq^{n-1} + tq(1 + q + \cdots + q^{2n-3})) \mu(\sigma). \end{aligned}$$

Hence (4.28) follows from (4.27). This completes the proof. $\blacksquare$

To prove formula (4.5) for the bivariate generating function of $(\text{sor}_D, \tilde{l}'_D)$, we recall another factorization of the diagonal sum $\sum_{\sigma \in D_n} \sigma$ due to Petersen. For $2 \leq j \leq n$, let

$$\Phi_j = 1 + \sum_{\substack{i \neq 0 \\ \bar{j} \leq i < j}} t_{ij}.$$

Proposition 4.8 For $n \geq 2$,

$$\sum_{\sigma \in D_n} \sigma = \Phi_2 \Phi_3 \cdots \Phi_n.$$

For an element $\sigma \in D_n$, we define another weight function

$$\nu(\sigma) = q^{\text{sort}_D(\sigma)} t^{\tilde{l}'_D(\sigma)}.$$

Again, the weight function ν is considered as a linear map. It can be checked that

$$\nu(\Phi_i) = 1 + tq^{i-1} + tq(1 + q + \cdots + q^{2i-3}) = 1 + tq^{i-1} + tq[2i - 2]_q. \quad (4.29)$$

We conclude this paper with a proof of (4.5).

Proof of (4.5) in Theorem 4.2. By Proposition 4.8 and (4.29), we find that (4.5) can be expressed in the following form

$$\nu(\Phi_2 \cdots \Phi_n) = \nu(\Phi_2) \cdots \nu(\Phi_n).$$

As in the proof of (4.4), we only need to show that

$$\nu(\Phi_2 \cdots \Psi_n) = \nu(\Phi_2 \cdots \Phi_{n-1}) \nu(\Phi_n).$$

It suffices to prove that

$$\nu(\sigma \cdot \Phi_n) = \nu(\sigma) \cdot \nu(\Phi_n), \quad (4.30)$$

for any $\sigma = \sigma_1 \cdots \sigma_{n-1} \in D_{n-1}$. Again, σ is considered as an element of D_n which fixes n . Since

$$\begin{aligned} \sigma \cdot \Phi_n &= \sigma_1 \cdots \sigma_{n-1} n + \sigma_1 \cdots \sigma_{n-2} n \sigma_{n-1} + \cdots + \sigma_1 n \cdots \sigma_{n-1} \sigma_2 + n \sigma_2 \cdots \sigma_{n-1} \sigma_1 \\ &\quad + \bar{n} \sigma_2 \cdots \sigma_{n-1} \bar{\sigma}_1 + \sigma_1 \bar{n} \cdots \sigma_{n-1} \bar{\sigma}_2 + \cdots + \bar{\sigma}_1 \cdots \sigma_{n-1} \bar{n}, \end{aligned}$$

we get

$$\begin{aligned} \nu(\sigma \cdot \Phi_n) &= \nu(\sigma_1 \cdots \sigma_{n-1} n) + \nu(\sigma_1 \cdots \sigma_{n-2} n \sigma_{n-1}) + \cdots + \nu(\sigma_1 n \cdots \sigma_{n-1} \sigma_2) + \nu(n \sigma_2 \cdots \sigma_{n-1} \sigma_1) \\ &\quad + \nu(\bar{n} \sigma_2 \cdots \sigma_{n-1} \bar{\sigma}_1) + \nu(\sigma_1 \bar{n} \cdots \sigma_{n-1} \bar{\sigma}_2) + \cdots + \nu(\bar{\sigma}_1 \sigma_2 \cdots \sigma_{n-1} \bar{n}) \\ &= \nu(\sigma) + qt \nu(\sigma) + \cdots + q^{n-2} t \nu(\sigma) + q^{n-1} t \nu(\sigma) \\ &\quad + q^{n-1} t \nu(\sigma) + q^n t \nu(\sigma) + \cdots + q^{2n-2} t \nu(\sigma) \\ &= (1 + tq^{n-1} + tq(1 + q + \cdots + q^{2n-3})) \nu(\sigma). \end{aligned}$$

Hence (4.30) follows from (4.29). This completes the proof. ■
